Spatial & Physical AI：Empowering the Future of Smart Cities

[1]Jae Won Cha, NAVER LABS

Naver Labs introduces how digital twin, spatial and physical AI, and robotics converge to form the foundation of next-generation urban environments. A digital twin precisely reconstructs the physical world in three dimensions and reproduces it within the cloud, enabling various machines—such as smartphones, AR glasses, robots, and autonomous vehicles—to perceive and understand spatial contexts. Through cloud connectivity with the digital twin, these machines employ spatial and physical AI to move autonomously or provide diverse services within real-world settings. This presentation explores the new forms of connectivity created by these technologies and discusses the expanded potential of smart buildings and future cities that emerge from their integration.
